Contents

1 Detailed Design

1.1 PM Modifier Module

This module will be called by Parser module and User Interface module for

- Adding a Virtual Machine(VM),
- Deleting a VM,
- Switching off a PM,
- Switching on a PM and
- Consolidation

1.1.1 Interface Data Structures

1. PMstruct

PMstruct

Different fields in PMstruct data structure are

1. PM_ID - final String
2. res_cap - integer
3. VM_list - array of type class VMstruct
4. onSate - integer

This is the data structure returned to status() function which is called by User Interface

1.1.2 Internal Data Structures

1. VMstruct

VMstruct

Different fields in VMstruct data structure are

1. VM_ID - final String
2. cap - integer

This is the structure used by PM modifier to create a VM.

1.1.3 Interface Functions

void deleteVM(VM_ID)
Description : The purpose of this function is to delete the VM which is passed as an input parameter to while calling this function.
Input parameters : The VM_ID of VM which has to be deleted.
Output parameters : NONE.
Return Values : None, because all the error conditions that may arise are handled by data validation in user interface.
Pseudocode :

```
1: void deleteVM(VM_ID)
2: for each PMstruct in PMarray do
3:    for each VMstruct in VMarray do
4:       if VM_ID matches then
5:          delete this VM
6:       end if
7:    end for
8: end for
```

void addVM(cap)
Description : This function checks the PM's if there is enough capacity available and if available adds the VM to it. If there is no enough capacity it returns an error.
Input parameters : The cap of VM which is to be added. The ID for VM is automatically generated by the function.
Output parameters : NONE.
Return Values : If sufficient capacity to add a VM is not available it returns **No enough capacity** error message
Pseudocode :

```
1: void addVM(cap)
2: for each PMstruct in PMarray do
3:    if res_cap ≤ 1 cap then
4:       create an ID for this VM
5:       add VM to this PM
6:    end if
7: end for
```

void consolidate()
Description : The function runs the consolidation algorithm to consolidate VM's in PM's and swithces off the PM's if any of the PM's become empty after consolidation.
Input parameters : NONE.
Output parameters : NONE.
Return Values : No possible error conditions
Pseudocode :

```
1: void consolidate()
2: quicksort(PMarray,lo,hi) {sorts PMs in decreasing order of their residual
   capacity}
3: for i from 0 to PMarray.lenght-1 do
4:    quicksort(PMarray[i].VMarray, lo, hi) {sorts VMs in decreasing order
      of their capacity}
5:    for each VMstruct in VMarray do
6:       for i from PMarray.lenght-1 to 0 do
7:          if PMarray[i].PMstruct.res_cap ≥ VMarray.VMstruct.cap then
8:             move VMstruct into this PMstruct's VMarray
9:          end if
10:      end for
11:   end for
12: end for
13: void quicksort(PMarray,lo,hi)
14: if lo < hi then
15:    p = pivot(PMarray,lo,hi)
16:    left, right = partition(PMarray, p, lo, hi)
17:    quicksort(PMarray, lo, left)
18:    quicksort(PMarray, right, hi)
19: end if
```

```
1: int partition(PMarray, left, right, pivotIndex)
2: pivotValue = PMarray[pivotIndex]
3: swap PMarray[pivotIndex] and PMarray[right]
4: storeIndex = left
5: for i from left to right - 1 do
6:    if PMarray[i] ≤ 1 pivotValue then
7:       swap PMarray[i] and PMarray[storeIndex]
8:       storeIndex = storeIndex + 1
9:    end if
10:   swap PMarray[storeIndex] and PMarray[right]
11: end for
12: return storeIndex
```

void switchOffPM(PM_ID)

Description : This function switches off the specified PM.

Input parameters : PM ID of the PM which has to be switched off.

Output parameters : NONE.

Return Values : Returns error if the VM's in the current PM can't be consolidated in to other PM's.

Pseudocode :

```
1: void switchOffPM(PM_ID)
2: for each PMstruct in PMarray do
3:    if PM_ID matches then
```

```
4:       change onState to OFF
5:    end if
6: end for
```

void switchOnPM(PM_ID)

Description : This function switches on the specified PM.
Input parameters : PM ID of the PM which has to be switched on.
Output parameters : NONE.
Return Values : No possible error condition.
Pseudocode :

```
1: void switchOnPM(PM_ID)
2: for each PMstruct in PMarray do
3:    if PM_ID matches then
4:       change onState to ON
5:    end if
6: end for
```
