# 1 Detailed Design

## 1.1 PM Modifier Module

This module will be called by Parser module and User Interface module for

- Adding a Virtual Machine(VM),
- Deleting a VM,
- Switching off a PM,
- Switching on a PM and
- Consolidation

### 1.1.1 Interface Data Structures

1. PMstruct

#### **PMstruct**

Different fields in PMstruct data structure are

1. PM\_ID - final String
2. res\_cap - integer
3. VM\_list - array of type class VMstruct
4. onSate - integer

This is the data structure returned to status() function which is called by User Interface

### 1.1.2 Internal Data Structures

1. VMstruct

#### **VMstruct**

Different fields in VMstruct data structure are

1. VM\_ID - final String
2. cap - integer

This is the structure used by PM modifier to create a VM.

### 1.1.3 Interface Functions

**void deleteVM(VM\_ID)**

**Description :** The purpose of this function is to delete the VM which is passed as an input parameter to while calling this function.

**Input parameters :** The VM\_ID of VM which has to be deleted.

**Output parameters :** NONE.

**Return Values :** None, because all the error conditions that may arise are handled by data validation in user interface.

**Pseudocode :**

```
1: void deleteVM(VM_ID)
2: for each PMstruct in PMarray do
3:   for each VMstruct in VMarray do
4:     if VM_ID matches then
5:       delete this VM
6:     end if
7:   end for
8: end for
```

**void addVM(cap)**

**Description :** This function checks the PM's if there is enough capacity available and if available adds the VM to it. If there is no enough capacity it returns an error.

**Input parameters :** The cap of VM which is to be added. The ID for VM is automatically generated by the function.

**Output parameters :** NONE.

**Return Values :** If sufficient capacity to add a VM is not available it returns **No enough capacity** error message

**Pseudocode :**

```
1: void addVM(cap)
2: for each PMstruct in PMarray do
3:   if  $res\_cap \leq 1\ cap$  then
4:     create an ID for this VM
5:     add VM to this PM
6:   end if
7: end for
```

**void consolidate()**

**Description :** The function runs the consolidation algorithm to consolidate VM's in PM's and switches off the PM's if any of the PM's become empty after consolidation.

**Input parameters :** NONE.

**Output parameters :** NONE.

**Return Values :** No possible error conditions

**Pseudocode :**

```

1: void consolidate(cap)
2: for each PMstruct in PMarray do
3:   if res_cap  $\leq$  1 cap then
4:     add VM to this PM
5:   end if
6: end for

```

**void switchOffPM(PM\_ID)**

**Description :** This function switches off the specified PM.

**Input parameters :** PM ID of the PM which has to be switched off.

**Output parameters :** NONE.

**Return Values :** Returns error if the VM's in the current PM can't be consolidated in to other PM's.

**Pseudocode :**

```

1: void switchOffPM(PM_ID)
2: for each PMstruct in PMarray do
3:   if PM_ID matches then
4:     change onState to OFF
5:   end if
6: end for

```

**void switchOnPM(PM\_ID)**

**Description :** This function switches on the specified PM.

**Input parameters :** PM ID of the PM which has to be switched on.

**Output parameters :** NONE.

**Return Values :** No possible error condition.

**Pseudocode :**

```

1: void switchOnPM(PM_ID)
2: for each PMstruct in PMarray do
3:   if PM_ID matches then
4:     change onState to ON
5:   end if
6: end for

```
